

How to interpret figures in victorias_figures:

- Tip off = game starts when hour = 0. Before 0 means pregame, after 0 is during game
- Horizontal dotted line represent even split aka .50 bid, .50 ask
- Y axis represents yes price.
    - In this graph, yes was at 0.42 ish, so the market had a higher probability of spurs losing before the game started
    - After the game started, there are spikes in yes prices/probabilities until the hour mark, where it sharply fell. Then it continues changing direction, but nets positive as the game ends
- Mention the the end, where it becomes all 1.0 on the y axis is due to the market closing/game being over if needed
- What to conclude: as time went on, bets became more aligned with the overall winner

    - Begins in confidence to pacers, favor significantly drops until 2 hour mark, where a huge reversal in confidence occurs.

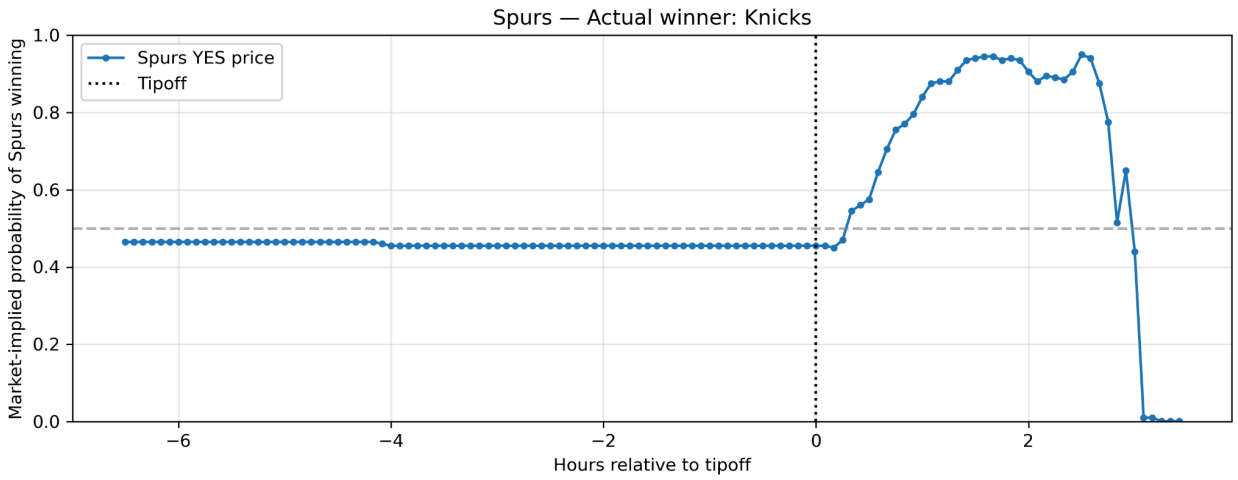

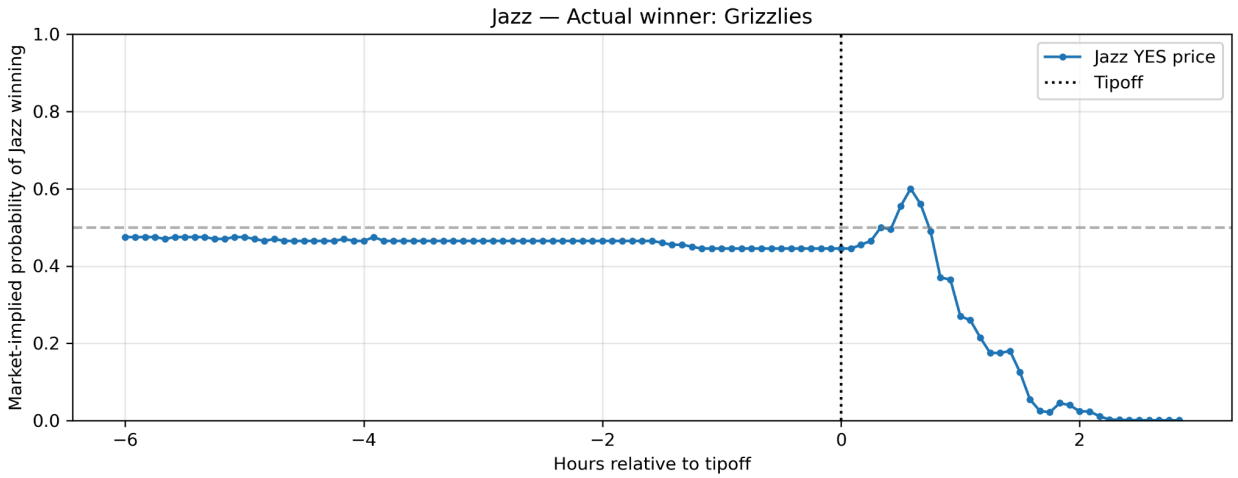

- ignore the weird sharp increase, i will change the graph tomorrow
- This shows that the market started off not confident in the kings aka yes price was low
    - And then near the end, the graph goes down, meaning the market confidence went to the opponent, or the Clippers.

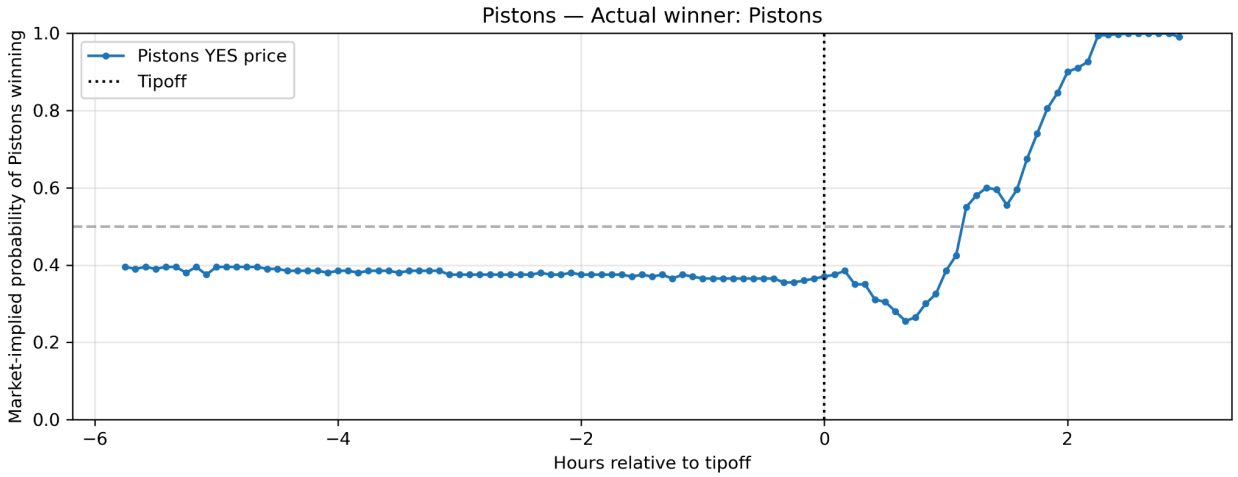

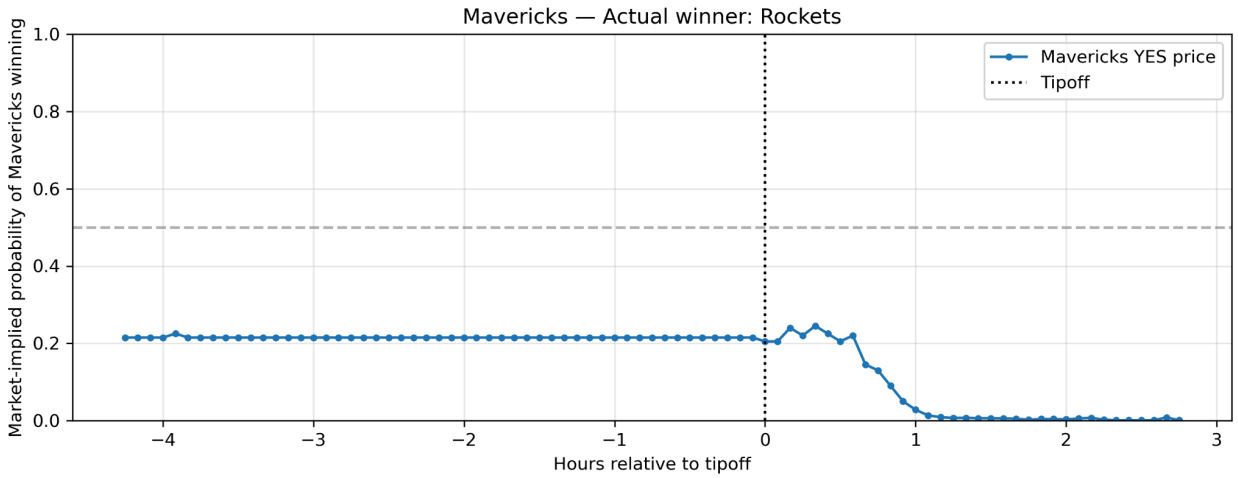

- This one of (maybe the only) one where the market was sure of a result for a majority of the game, but the game results were the opposite
- Market probability for spurs win was high, but knicks ended up winning

- Smaller, more temporary scale of what happened in spur v knicks

Overall message: in 8/9 games, there is some volatility in the direction of probabilities, but the markets general move in the winning direction as time goes on. There is only one case where this is not what happened, in the spurs v knicks game.
